Abstract

We use stochastic geometry to analyze the performance of a partial decode-and-forward (PDF) relaying scheme applied in a user-assisted relaying setting, where an active user relays data through another idle user in uplink cellular communication. We present the geometric model of a network deploying user-assisted relaying and propose two geometric cooperation policies for fast and slow fading channels. We analytically derive the cooperation probability for both policies. This cooperation probability is further used in the analytical derivation of the moments of intercell interference power caused by system-wide deployment of this user-assisted PDF relaying. We then model the inter-cell interference power statistics using the Gamma distribution by matching the first two moments analytically derived. This cooperation and interference analysis provides the theoretical basis for quantitatively evaluating the performance impact of user-assisted relaying in cellular networks. We then numerically evaluate the average transmission rate performance and show that user-assisted relaying can significantly improve per-user transmission rate despite of increased inter-cell interference. This transmission rate gain is significant for active users near the cell edge and further increases with higher idle user density, supporting user-assisted relaying as a viable solution to crowded population areas.

1 Introduction

1.1 Motivation

Mobile subscribers operators and continual driven customer by the increasing demand for number new and of better services place pressing requirements on the underlying wireless technologies to provide high data rates and wide coverage. Future generation networks that promise higher data rates and multifold increase in system capacity include 3GPP Long Term Evolutionfk??Advanced (LTE-A, 4G) and the emerg- ing 5G systems. The fourth generation (4G) wireless systems were designed to fulfill the requirements of the International Mobile Telecommunications fk?? Advanced (IMT-A). LTE as a practical 4G wireless system has been recently deployed in some countries and LTE-A is expected to be deployed soon around the globe [1]. It is well established that 4G networks have just reached the theoretical limit on the data rate with current technologies. These technologies are being complemented in the fifth generation (5G) wireless systems by designing and developing new radio concepts to accommodate higher data rates, larger network capacity, higher energy efficiency, and higher mobility necessary to meet the new and challenging requirements of new wireless applications. 5G wireless systems are expected to support peak data rate of 10 Gb/s for low mobility and 1 Gb/s for high mobility. These networks are expected to be standardized and deployed around and beyond 2020. Various promising technologies are proposed for 5G wireless communication systems such as massive MIMO, energy-efficient communications, Device-to- Device (D2D) communications, millimeterwave (mmWave), and cognitive radio networks [1]fi?![3].

2 Partial Decode-and-Forward Relaying

In this section, we discuss the signal design, channel model and achievable rate of PDF relaying scheme.

2.1 Signal Design

Consider a source \mathcal{S} , its relay \mathcal{R} and the destination \mathcal{D} . Each transmission block is divided into two phases: 1. broadcast transmission in which \mathcal{S} broadcasts to both \mathcal{R} and \mathcal{D} . 2. multiple access transmission in which both \mathcal{S} and \mathcal{R} transmit to \mathcal{D} . In each block of transmission, \mathcal{S} splits its information into a common part and a private part. The common part is encoded via U_s^b in the 1st phase and $U_s^{m_1}$ in the 2nd phase; and the private part is encoded via $V_s^{m_2}$ in the 2nd phase. The relay \mathcal{R} decodes the information sent by \mathcal{S} in first phase and encodes the same information using $U_s^{m_1}$ in the 2nd phase.

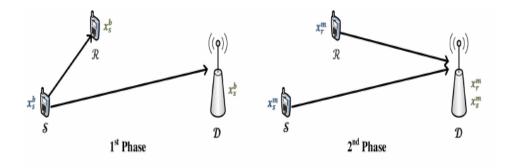

Figure 1: Transmission phases in PDF relaying

The signals transmitted by \mathcal{R} and \mathcal{S} are as follows:

Phase 1:
$$x_s^b = \sqrt{P_s^b} U_s^b$$
, (1)

Phase 2:
$$x_r^m = \sqrt{P_r^m} U_s^{m_1},$$
 (2)

$$x_s^m = \sqrt{P_s^{m_1}} U_s^{m_1} + \sqrt{P_s^{m_2}} V_s^{m_2} \tag{3}$$

All codewords above are picked from independent Gaussian codebooks with zero mean and unit variance.

Power Constraints: Let P_s and P_r be the transmit powers of S and R respectively and α_1 be the fraction of transmission time allocated to first phase, then the following average power constraints should to be satisfied:

$$\alpha_1 P_s^b + \alpha_2 P_s^m = Ps, \quad \alpha_2 P_r^m = P_r \tag{4}$$

where $\alpha_2 = 1 - \alpha_1$

2.2 Channel Model

Considering the transmit signals presented above and assuming flat fading over the two phases, the received signals at \mathcal{R} and \mathcal{D} during first phase are

$$Y_r^b = h_{sr} x_s^b + Z_r^b, \quad Y_d^b = h_{sd} x_s^b + Z_d^b$$
 (5)

where b denotes broadcast mode, Z_r^b and Z_d^b are i.i.d circularly-symmetric complex gaussians with mean 0 and variance $\sigma^2 - \mathcal{CN}(0, \sigma^2)$ that represent noises at \mathcal{R} and \mathcal{D} .

Similarly the received signal at \mathcal{D} during second phase can be modelled as

$$Y_d^m = h_{sd} x_s^m + h_{rd} x_r^m + Z_d^m (6)$$

here m denotes multicast transmission; all others have usual meaning. The above expression is true only if \mathcal{D} has knowledge about the phase offset between \mathcal{S} and \mathcal{R} . This assumption is justified by noting that the phase offset between the two nodes can be estimated at base station.

2.3 Achievable Rate

With transmit signals in equations 1- 3 and joint ML decoding rule at \mathcal{D} , the achievable rate for this relaying scheme is:

$$R_{PDF} \le \min(C_1 + C_2, C_3) \tag{7}$$

where
$$C_1 = \alpha_1 \log \left(1 + |h_{sr}|^2 P_s^b \right),$$
 (8)

$$C_2 = \alpha_2 \log \left(1 + |h_{sd}|^2 P_s^{m_2} \right), \tag{9}$$

$$C_3 = \alpha_1 \log \left(1 + |h_{sd}|^2 P_s^b \right) + \alpha_2 \log \left(1 + |h_{sd}|^2 P_s^{m_2} + \left(|h_{sd}| \sqrt{P_s^{m_1}} + |h_{rd}| \sqrt{P_r^m} \right)^2 \right)$$
(10)

 C_1 represents the rate of the common part that can be decoded at \mathcal{R} , C_2 the private part that can be decoded at \mathcal{D} provided the common part has been decoded correctly, and C_3 both the common and private parts that can be jointly decoded at \mathcal{D} . These rates are achievable provided full CSIR at all receivers and the source-relay phase offset knowledge.

Now that we know what PDF relaying scheme is and the achievable rate, let us see how this scheme performs in cellular networks. To analyse system performance under PDF relaying, we need to know network geometry i.e., how the users and base stations are distributed, how many users can take advantage of relaying, how users identify a potential relay etc. In the next couple of sections we describe network geometry, received signals and interference model when relaying is deployed in the whole network, and cooperation policies.

3 Cellular Network Geometry and User-Assisted Relaying

3.1 Network geometry model

Consider a cellular system which consists of multiple cells, each cell has a single base station and each base station serves multiple users. Each of the users uses a distinct frequency block. Each user is served by the single base station that is closest to that user.

We use stochastic geometry to describe the uplink cellular network as shown in Fig. 5. We assume that the active users in different cells that use the same resource block and cause interference to each other are distributed on a two-dimensional plane according to a homogeneous and stationary Poisson point process (PPP) Φ_1 with intensity λ_1 . The set of user equipments(UEs) that are in idle state and can participate in relaying are distributed according to another PPP Φ_2 with intensity λ_2 . We assume Φ_1 and Φ_2 are independent. Furthermore, under the assumption that each BS serves a single mobile in a given resource block, the BS should be closer to its served UE than to any other UE. Therefore we assume each BS is uniformly distributed in the Voronoi cell of its served UE. Fig. 2 shows an example layout of the model.

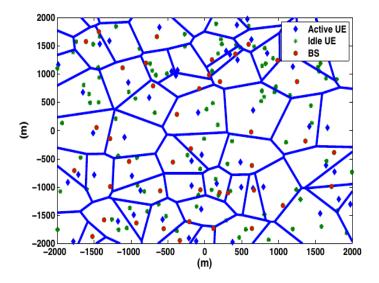

Figure 2: Sample layout of a cellular network ($\lambda_2 = 2\lambda_1$)

Channel Model 3.2

In this section, we describe the channel model when PDF relaying is deployed in cellular network. In this case, there will be out-of-cell inteference in addition to noise. The interference is due to frequency reuse in other cells.

Consider i^{th} cell, we model the received signals at the relay and base station in this cell during 1st phase as

$$Y_{r,i}^{b} = h_{sr}^{(i)} x_{s,i}^{b} + I_{r,i}^{b} + Z_{r,i}^{b},$$

$$Y_{d,i}^{b} = h_{sd}^{(i)} x_{s,i}^{b} + I_{d,i}^{b} + Z_{d,i}^{b}$$
(11)

where $I^b_{r,i}$ and $I^b_{d,i}$ represent the interference received at the i^{th} relay and destination. In second phase of the transmission, the received signal at the BS can be modelled as

$$Y_{d,i}^{m} = h_{sd}^{(i)} x_{s,i}^{m} + h_{rd}^{(i)} x_{r,i}^{m} + I_{d,i}^{m} + Z_{d,i}^{m}$$
(12)

Interference

To model interference, we assume prefect frame synchronization. LTE-Advanced imposes very strict requirements on synchronization anyway. Interference at the relay during first phase and at the destination(BS) during first and second phases can be expressed as

$$I_{r,i}^{b} = \sum_{k \neq i} B_{k} h_{sr}^{(k,i)} x_{s,k}^{b} + (1 - B_{k}) h_{sr}^{(k,i)} x_{s,k},$$

$$I_{d,i}^{b} = \sum_{k \neq i} B_{k} h_{sd}^{(k,i)} x_{s,k}^{b} + (1 - B_{k}) h_{sd}^{(k,i)} x_{s,k},$$

$$I_{d,i}^{m} = \sum_{k \neq i} B_{k} \left(h_{sd}^{(k,i)} x_{s,k}^{m} + h_{rd}^{(k,i)} x_{r,k}^{m} \right) + (1 - B_{k}) h_{sd}^{(k,i)} x_{s,k}$$

$$(13)$$

the summation is over all active users. Here, $h_{sd}^{(k,i)}$ and $h_{rd}^{(k,i)}$, respectively, are the channel fading from the k^{th} active UE in Φ_1 and the associated relaying UE in Φ_2 to the BS associated with the i^{th} active UE in Φ_1 ; and $h_{sr}^{(k,i)}$ is the channel fading from the k^{th} active UE in Φ_1 to the relaying UE associated with the i^{th} active UE in Φ_1 .

 B_k in above expressions is a Bernoulli random variable with success probability ρ . $B_k=1$ is used to indicate the k^{th} active UE's decision to exploit the help of another idle UE, a relay, and apply the relaying transmission strategy, and $B_k=0$ indicates that the k^{th} UE has no relay. In section 4, we derive the cooperation probability ρ for different cooperation policies.

For a given setting of nodes locations, based on the interference model in Eq. 13, we can use the fact that interference at either the relay or destination is the sum of an infinite number of signals undergoing independent fading from nodes distributed in the infinite 2-D plane and use the law of large numbers to approximate the interference as a complex Gaussian distribution. Also, since the transmitted codewords complex Gaussian with zero mean, mean of interference is zero. To fully characterize interference as a complex Gaussian distribution, we define their distributions as $I_{d,i}^b \sim \mathcal{CN}(0, \mathcal{Q}_{d,i}^b), I_{d,i}^m \sim \mathcal{CN}(0, \mathcal{Q}_{d,i}^m)$, and $I_{r,i}^b \sim \mathcal{CN}(0, \mathcal{Q}_{r,i})$ with the variances derived later in Section 5. The power of these interference terms which correspond to the variance of the Gaussian random variables are function of node locations and hence vary with different network realizations.

3.4 Equivalent Standard Channel Model

Using the interference model discussed above, we can convert the channel model in case of relaying into the standard form to capture the effects of interference into the channel fading as

$$\begin{split} \tilde{Y}_{r,i}^{b} &= \tilde{h}_{sr}^{(i)} x_{s,i}^{b} + \tilde{Z}_{r,i}^{b}, \\ \tilde{Y}_{d,i}^{b} &= \tilde{h}_{sd}^{(i)} x_{s,i}^{b} + \tilde{Z}_{d,i}^{b}, \\ \tilde{Y}_{d,i}^{m} &= \tilde{h}_{sd}^{(i)} x_{s,i}^{m} + \tilde{h}_{rd}^{(i)} x_{r,i}^{m} + \tilde{Z}_{d,i}^{m}, \end{split}$$

where the new channel fading terms are defined as

$$\tilde{h}_{sr}^{(i)} = \frac{h_{sr}^{(i)}}{\sqrt{\mathcal{Q}_{r,i} + \sigma^2}}, \quad \tilde{h}_{sd}^{(b,i)} = \frac{h_{sd}^{(i)}}{\sqrt{\mathcal{Q}_{d,i}^b + \sigma^2}} \quad \tilde{h}_{sd}^{(m,i)} = \frac{h_{sd}^{(i)}}{\sqrt{\mathcal{Q}_{d,i}^m + \sigma^2}}, \quad \tilde{h}_{rd}^{(i)} = \frac{h_{rd}^{(i)}}{\sqrt{\mathcal{Q}_{d,i}^m + \sigma^2}}$$

and the noise terms are now all $\mathcal{CN}(0,1)$. Using these equivalent standard channels, we can compute the transmission rate as in Eq. 7

4 Cooperation Policies and Probability

In this section, we look at three cooperation policies: an ideal policy E_1 , a pure geometric policy E_2 and a hybrid policy E_3 that defines whether an active UE should select an inactive UE to use it in PDF relaying. Also, expressions for cooperation probabilities of E_2 and E_3 are derived.

4.1 Policies

4.1.1 Ideal Policy E_1

The ideal cooperation policy E_1 requires the active UE nodes to know instantaneous SINRs of the relay link(S - R) and the direct link(S - D). The policy is defined as

$$E_1 = \left\{ |\tilde{h}_{(sr)}^{(k)}|^2 \ge |\tilde{h}_{(sd)}^{(k)}|^2 \right\}$$
$$\simeq \left\{ \frac{g_{sr}r_2^{-\alpha}}{Q_{r,k}} \ge \frac{g_{sd}r_1^{-\alpha}}{Q_{d,k}^b} \right\}$$

where r_1 and r_2 denote the direct distance between S and D and cooperation distance between S and its closest idle UE, respectively and α is pathloss exponent. This event E_1 identifies whether an idle UE will be associated as a relay for the k^{th} UE and participate in transmission. Noise variance σ^2 is ignored since interference dominates.

Since interference at relay and destination during first phase is more or less the same and g_{sr} , g_{sd} are identically distributed, we can safely ignore them and propose a policy that depends only on distances.

4.1.2 Pure Geometric Policy E_2

This policy is defined as

$$E_2 = \{ r_2 \le r_1, D \le r_1 \} \tag{14}$$

where D is the distance between \mathcal{R} and \mathcal{D} . In words, if source's (active UE's) nearest idle neighbour is in the intersection region of two circles of radius r_1 centered at source and destination, then that idle UE will be chosen to act as a relay.

 E_2 is more practical than policy E_1 in the sense that it does not require full knowledge of both the channel fading and the interference at the decision making node. Instead, it only requires the decision making nodes to know the distances from the active user to the nearest idle user and to the base station. It represents a practical decision making strategy for fast fading channels, requiring no knowledge of the channel fading.

4.1.3 Hybrid Policy E_3

This policy is proposed for slow fading channels where small scale fading parameters estimation and their feedback to the decision making node is feasible.

$$E_3 = \{ g_{sd} r_1^{-\alpha} \le g_{sr} r_2^{-\alpha}, D \le r_1 \}$$
 (15)

Note that this cooperation policy is still independent of the interference as in the pure geometric cooperation policy E_2 .

4.2 Cooperation Probabilities

In this part of the section we derive cooperation probabilities ρ_2 and ρ_3 for the policies E_2 and E_3 respectively. For the ideal policy E_1 , analytic evaluation of the cooperation probability is rather complicated because of the interdependency between the cooperation decision and con-sequential interference among different cells, hence we use numerical simulations instead. Consider a random BS and its associated active UE. The distribution of the distance r_1 between the i^{th} UE and its associated BS can be shown to be Rayleigh distributed directly from the null probability of a two dimensional PPP distribution.

we can assume due to the stationarity of the PPP, i.e., location of the origin doesn't change the distribution of points, and the independence of Φ_2 from BSs distribution that the location of the UE associated with the BS under study represents the origin point of Φ_2 . Then, each UE in Φ_1 chooses the closest UE in Φ_2 to assist it in relaying its message to the serving BS. Hence, similar to source-to- destination distance, the distribution of the source-to-relay distance r_2 between the i^{th} UE and its associated relaying UE can be also shown to be Rayleigh distributed from the null probability of a two dimensional PPP. Therefore,

$$f_{r_1}(r_1) = 2\pi \lambda_1 r_1 e^{-\lambda_1 \pi r_1^2},$$

$$f_{r_2}(r_2) = 2\pi \lambda_2 r_2 e^{-\lambda_2 \pi r_2^2}$$
(16)

Theorem 1. Cooperation Probabilities. The probability of deploying user-assisted relaying for a randomly located active user within a cell can be evaluated as follows:

i. For policy E_2

$$\rho_2 = \int_{-\pi/2}^{-\pi/3} \frac{2\lambda_2 cos^2 \psi_0}{\pi(\lambda_1 + 4\lambda_2 cos^2 \psi_0)} d\psi_0 + \int_{\pi/3}^{\pi/2} \frac{2\lambda_2 cos^2 \psi_0}{\pi(\lambda_1 + 4\lambda_2 cos^2 \psi_0)} d\psi_0 + \frac{\lambda_2}{3(\lambda_1 + \lambda_2)}$$
(17)

ii. For policy E_3

$$\rho_{3} = \int_{0}^{2} f_{\beta}(z) \int_{-\pi/2}^{-\cos^{-1}(z/2)} \frac{2\lambda_{2}\cos^{2}\psi_{0}}{\pi(\lambda_{1} + 4\lambda_{2}\cos^{2}\psi_{0})} d\psi_{0} dz$$

$$+ \int_{0}^{2} f_{\beta}(z) \int_{\cos^{-1}(z/2)}^{\pi/2} \frac{2\lambda_{2}\cos^{2}\psi_{0}}{\pi(\lambda_{1} + 4\lambda_{2}\cos^{2}\psi_{0})} d\psi_{0} dz$$

$$+ \int_{0}^{2} f_{\beta}(z) \frac{\lambda_{2}z^{2}\cos^{-1}(z/2)}{\pi(\lambda_{1} + \lambda_{2}z^{2})} dz$$

$$+ \int_{2}^{\infty} f_{\beta}(z) \int_{-\pi/2}^{\pi/2} \frac{2\lambda_{2}\cos^{2}\psi_{0}}{\pi(\lambda_{1} + 4\lambda_{2}\cos^{2}\psi_{0})} d\psi_{0} dz$$

where $\beta=\left(rac{g_{sr}}{g_{sd}}
ight)^{1/lpha}$ and $f_{eta}(z)$ is pdf of eta which can be shown to be

$$f_{\beta}(z) = \frac{\alpha z^{\alpha - 1}}{(1 + z^{\alpha})^2} \tag{18}$$

Proof. i

$$\begin{split} \rho_2 &= \mathbb{P}\{E_2\} \\ &= \mathbb{P}\{r_2 \le r_1, r_1^2 + r_2^2 - 2r_1r_2cos\psi_0 \le r_1^2\} \\ &= \mathbb{P}\{r_2 \le r_1, r_2 \le 2r_1cos\psi_0\} \end{split}$$

when $|\psi_0| < \pi/3$, $r_1 < 2r_1 cos \psi_0 \Rightarrow \text{ if } r_2 < r_1$, r_2 satisfies both inequalities. Accordingly, we define \mathcal{E}_1 and \mathcal{E}_2 as follows

$$\mathcal{E}_{1} = (2\pi)^{2} \lambda_{1} \lambda_{2} \int_{0}^{\infty} \int_{0}^{2r_{1}cos\psi_{0}} r_{1}r_{2}e^{-\pi(\lambda_{1}r_{1}^{2} + \lambda_{2}r_{2}^{2})} dr_{2}dr_{1}$$

$$= \frac{2\lambda_{2}cos^{2}\psi_{0}}{\pi(\lambda_{1} + 4\lambda_{2}cos^{2}\psi_{0})}$$

$$\mathcal{E}_{2} = (2\pi)^{2} \lambda_{1} \lambda_{2} \int_{0}^{\infty} \int_{0}^{r_{1}} r_{1}r_{2}e^{-\pi(\lambda_{1}r_{1}^{2} + \lambda_{2}r_{2}^{2})} dr_{2}dr_{1}$$

$$= \frac{\lambda_{2}}{2\pi(\lambda_{1} + \lambda_{2})}$$

Now,
$$\rho_2 = \int_{-\pi/3}^{\pi/3} \mathcal{E}_2 d\psi_0 + 2 \int_{\pi/3}^{\pi/2} \mathcal{E}_1 d\psi_0$$

= $\frac{\lambda_2}{3(\lambda_1 + \lambda_2)} + 2 \int_{\pi/3}^{\pi/2} \mathcal{E}_1 d\psi_0$

ii.

$$\rho_3 = \mathbb{P}\{E_3\} \tag{19}$$

$$= \mathbb{P}\left\{r_2 \le \left(\frac{g_{sr}}{g_{sd}}\right)^{1/\alpha} r_1, r_1^2 + r_2^2 - 2r_1 r_2 cos\psi_0 \le r_1^2\right\} \tag{20}$$

$$= \mathbb{P}\{r_2 \le \beta r_1, r_2 \le 2r_1 \cos \psi_0\} \tag{21}$$

$$= \mathbb{P}\{r_2 \le 2r_1 \cos \psi_0\} \qquad \text{for } \beta > 2 \tag{22}$$

$$= \mathbb{P}\{r_2 \le \beta r_1\} \qquad \text{for } \beta < 2 \text{ and } |\psi_0| < \cos^{-1}(\beta/2)$$
 (23)

$$= \mathbb{P}\{r_2 \le 2r_1 \cos \psi_0\} \qquad \text{for } \beta < 2 \text{ and } \cos^{-1}(\beta/2) < |\psi_0| < \pi/2$$
 (24)

$$\therefore \rho_3 = 2 \int_0^2 f_{\beta}(z) \int_{\cos^{-1}(z/2)}^{\pi/2} \mathcal{E}_1 d\psi_0 dz + \int_0^2 f_{\beta}(z) \int_{-\cos^{-1}(z/2)}^{\cos^{-1}(z/2)} \mathcal{E}_3 d\psi_0 dz$$
 (25)

$$+\int_{2}^{\infty} f_{\beta}(z) \int_{-\pi/2}^{\pi/2} \mathcal{E}_{1} d\psi_{0} dz \tag{26}$$

 \mathcal{E}_1 is defined in part i. of the proof and $\mathcal{E}_3 = \frac{\lambda_2 z^2}{2\pi(\lambda_1 + \lambda_2 z^2)}$ which is nothing but \mathcal{E}_2 with $\lambda_2 = \lambda_2 z^2$. $f_{\beta}(z)$, the pdf of β , can be obtained as follows

$$\begin{split} F_{\beta}(z) &= \mathbb{P}\bigg\{\bigg(\frac{x_1}{x_2}\bigg)^{1/\alpha} \leq z\bigg\} = \mathbb{P}\{x_1 \leq z^{\alpha}x_2\} \\ &= \int_0^{\infty} \int_0^{z^{\alpha}x_2} e^{-(x_1 + x_2)} dx_1 dx_2 \quad \text{ since } g_{sr}, g_{sd} \sim Exp(1) \\ &= 1 - \frac{1}{1 + z^{\alpha}}, \qquad z \in [0, \infty) \end{split}$$

The pdf $f_{\beta}(z)$ is then obtained by differentiating $F_{\beta}(z)$:

$$f_{\beta}(z) = \frac{dF_{\beta}(z)}{dz} = \frac{\alpha z^{\alpha - 1}}{(1 + z^{\alpha})^2} \quad z \in [0, \infty)$$

5 Interference Analysis

User-assisted relaying actually increases the amount of out- of-cell interference in the network as some idle users are now transmitting when relaying information of active users. It is therefore necessary to understand this out-of-cell interference power, particularly its distribution, in order to assess the overall impact of user-assisted relaying on system performance.

5.1 First Two Moments of Interference Power

Since it is difficult to describe the exact distribution of out-of-cell interference power, here we choose to model the interference power to the cell under study as a Gamma distribution by fitting the first two moments of the interference power analytically developed using stochastic geometry of the field of interferers outside that cell. The expressions

for interference power can be developed from Eqs. 13.

$$Q_{d,i}^{b} = \sum_{k \neq i} B_k \left| h_{sd}^{(k,i)} \right|^2 P_{s,k}^{b} + (1 - B_k) \left| h_{sd}^{(k,i)} \right|^2 P_{s,k}$$
(27)

$$Q_{d,i}^{m} = \sum_{k \neq i} \left[B_{k} \left(\left| h_{sd}^{(k,i)} \right|^{2} P_{s,k}^{m} + \left| h_{rd}^{(k,i)} \right|^{2} P_{r,k}^{m} \right) \right] + (1 - B_{k}) \left| h_{sd}^{(k,i)} \right|^{2} P_{s,k}$$
(28)

$$Q_{r,i} = \sum_{k \to i} B_k \left| h_{sr}^{(k,i)} \right|^2 P_{s,k}^b + (1 - B_k) \left| h_{sr}^{(k,i)} \right|^2 P_{s,k}$$
(29)

Theorem 2. Interference Power Statistics For network-wide deployment of user-assisted relaying, the out-of-cell interference generated at the destination BS and the relaying UE have the following statistics:

i. The first two moments, mean and variance, of interference power at the destination BS during the 1st and 2nd phase, respectively, are

$$\mathbb{E}[\mathcal{Q}_{d,i}^b] = \frac{2\pi\lambda_1\zeta_1}{\alpha - 2}R_c^{2-\alpha}, \qquad \mathbb{E}[\mathcal{Q}_{d,i}^m] = \frac{2\pi\lambda_1\zeta_3}{\alpha - 2}R_c^{2-\alpha}$$
(30)

$$var[\mathcal{Q}_{d,i}^b] = \frac{\pi \lambda_1 \zeta_2}{\alpha - 1} R_c^{2(1-\alpha)}, \qquad var[\mathcal{Q}_{d,i}^m] = \frac{\pi \lambda_1 \zeta_4}{\alpha - 1} R_c^{2(1-\alpha)}$$

$$(31)$$

ii. The first two moments, mean and variance, of interfer- ence power at the idle UE associated as a relay with the ith active UE are

$$\mathbb{E}[\mathcal{Q}_{r,i}] = \lambda_1 \zeta_1 \int_0^{2\pi} \int_{R_c}^{\infty} (r^2 + D^2 - 2rD\cos\theta)^{\alpha/2} r dr d\theta \tag{32}$$

$$var[\mathcal{Q}_{r,i}] = \lambda_1 \zeta_2 \int_0^{2\pi} \int_{R_c}^{\infty} (r^2 + D^2 - 2rD\cos\theta)^{\alpha/2} r dr d\theta$$
(33)

where
$$\zeta_1 = \rho_1 P_{s,k}^b + (1 - \rho_1) P_{s,k}$$
 (34)

$$\zeta_2 = 2[\rho_1(P_{sk}^b)^2 + (1 - \rho_1)P_{sk}^2],\tag{35}$$

$$\zeta_3 = \rho_1 (P_{s,k}^m + P_{r,k}^m) + (1 - \rho_1) P_{s,k}, \tag{36}$$

$$\zeta_4 = 2[\rho_1(P_{s,k}^m + P_{r,k}^m)^2 + (1 - \rho_1)P_{s,k}^2 - \rho_1P_{s,k}^mP_{r,k}^m]$$
(37)

Proof.

$$\begin{split} \mathbb{E}[\mathcal{Q}_{d,i}^b] &= -\frac{\partial \mathcal{L}_{\mathcal{Q}_{d,i}^b}(s)}{\partial s}\bigg|_{s=0}, \\ \text{var}[\mathcal{Q}_{d,i}^b] &= -\frac{\partial^2 \mathcal{L}_{\mathcal{Q}_{d,i}^b}(s)}{\partial s^2}\bigg|_{s=0} - \left(\mathbb{E}\big[\mathcal{Q}_{d,i}^b\big]\right)^2 \end{split}$$

where $\mathcal{L}_{\mathcal{Q}_{d,i}^b}(s)$ is the Laplace transform of $\mathcal{Q}_{d,i}^b$ and $R_c=1/2\sqrt{\lambda_1}$ is the cell radius. Means and variances of $\mathcal{Q}_{d,i}^m$, $\mathcal{Q}_{r,i}$ can be calculated similarly.

From the above results for interference power statistics, the interference power is directly proportional to both the active users density, λ_1 , and the transmission power levels represented by ζ_i , $i \in [1:4]$ in Eqs. 34 - 37

5.2 Modelling Interference Power Distribution

A parameterized probability distribution, which includes a wide variety of curve shapes, is useful in the representation of data when the underlying model is unknown or difficult to obtain in closed form. A parameterized probability distribution is usually characterized by its flexibility, generality, and simplicity. Although distributions are not necessarily determined by their moments, the moments often provide useful information and are widely used in practice. It is shown that the Gamma distribution is a good approximation for the interference when the point under study is closer to the cell center, but fails to represent the actual interference distribution whenever the point under study is exactly at the cell edge. We use the same approach here and match a Gamma distribution to the first two moments of the interference power terms derived earlier in Theorem 2.

5.2.1 Gamma Distribution

The Gamma distribution is specified by a shape parameter k and a scale parameter θ . The pdf of a Gamma distributed RV $\gamma[k,\theta]$ is defined as

$$F_{\gamma}(q|k,\theta) = \frac{q^{k-1}e^{(-q/\theta)}}{\theta^k\Gamma(k)}$$

where the Gamma function $\Gamma(t)$ is defined as $\Gamma(t)=\int_0^\infty x^{t-1}e^{-x}dx$. The mean and variance of $\gamma[k,\theta]$ are $k\theta$ and $k\theta^2$ respectively.

Since we know mean and variance of interference powers, we can estimate the shape and scale parameters by using the formulae:

$$k_i = \frac{(\mathbb{E}[\mathcal{Q}_i])^2}{\text{var}[\mathcal{Q}_i]}, \theta_i = \frac{\text{var}[\mathcal{Q}_i]}{\mathbb{E}[\mathcal{Q}_i]}$$
(38)

6 Simulations and Results

Simulations were done on MATLAB. Given λ_1 and λ_2 ,

6.1 Simulation Setting

 $P_{s,i}=P_{r,i}; P_{s,i}^b=P_{s,i}^m$ and $P_{s,i}^{m_1}=\beta_1 P_{s,i}^m$ and $P_{s,i}^{m_2}=(1-\beta_1)P_{s,i}^m$ are allocated optimally to maximize the transmission rate of the active user. To do this, rate is expressed as a function of β_1 and minimized negative rate using MATLAB tool fminrnd

6.2 Results

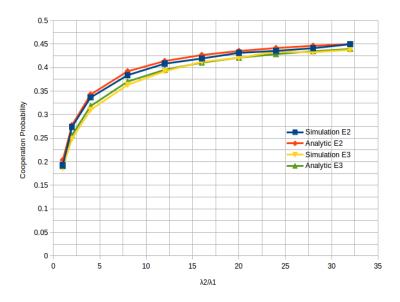

Figure 3: Cooperation probabilities of E_2 , E_3 versus user density ratio

From the above graph we can see that cooperation probability of both policies increases with user density ratio (λ_2/λ_1) and reach a maximum of 0.5 for very large user density ratio. Also, the analytic and simulations results closely match.

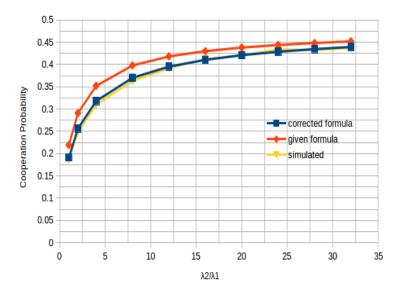

Figure 4: Corrected cooperation probability of E_3

In the published paper, the analytic result for cooperation probability of E_3 has an error. The correction being using \mathcal{E}_3 instead of \mathcal{E}_2 in eq. 26. The corrected analytic result matches the simulation result as can be seen in the above figure.

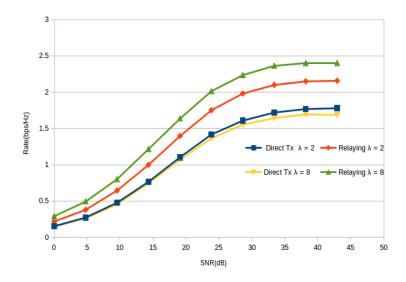

Figure 5: Average rate per user; $\lambda = \lambda_2/\lambda_1$

From the above figure, we can clearly see that average rate per user has increased when PDF relaying is deployed over the whole network. The rate also increases as user density ratio is increased but we caan't sure whether the rate keeps increasing with λ . It might happen that the rate decreases for very large user ratio density due to increase in interference.
